ABSTRACT

Ajax, which stands for **Asynchronous Javascript And XML**, is a combined technologies of combined of HTML + CSS for presenting information on to the web, JavaScript is for dynamically interacting change with the information presented at the client site and XML and XSLT object to manipulate data asynchronously with the web server.

A Messaging system allows staff to communicate with any department in the company by submitting messages via company internal system like Content Management System (CMS). This system implementing with AJAX technology so that it look and feel like desktop application needed no page refreshes, no flickering in the browser and no waiting. With Ajax, user is able to communicate with the server behind the scenes, grab the data and display it instantly in a web page.

CHAPTER 1: INTRODUCTION

1.1 Introduction

Making Web applications look and feel like desktop applications is what this project's all about – that's what Ajax does. Although Web development is getting more and more popular, users still experience the nasty part of having to click a button, wait until a new page loads, click another button, and wait until a new page loads, and so on.

With Ajax, you communicate with the server behind the scenes, grab the data or information users requested and display it instantly in a Web page – no page refreshes needed, no flickering in the browser, no waiting. That's what the research about; at last it lets Web applications start to look like desktop applications. Web messaging application software can have the same look and feel of software on the user's desktop.

A traditional desktop application. Messaging system with J2EE technology with embedded AJAX technology, users will realize that a new breed of dynamic web applications is emerging. These applications look and act very similar to traditional desktop applications without relying on plug-ins or browser-specific features. Web messaging applications have traditionally been a set of HTML pages that must be reloaded to change any portion of the content. Technologies such as JavaScript programming language and cascading style sheets (CSS) have matured to the point where they can be used effectively to create very dynamic web applications that will work on all of the major browsers. Any web application with enable AJAX techniques to be more rich and interactive like desktop applications.

By using JavaScript technology, an HTML page can asynchronously make calls to the server from which it was loaded and fetch XML documents. The XML
